

Calibration diagnostics at the selected strength (ratio 0.02) - not the forecasting result

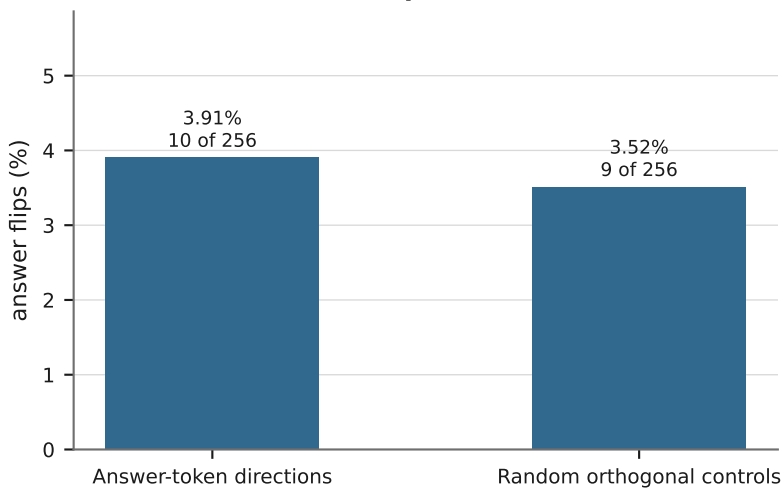

Signed effect is centred near zero

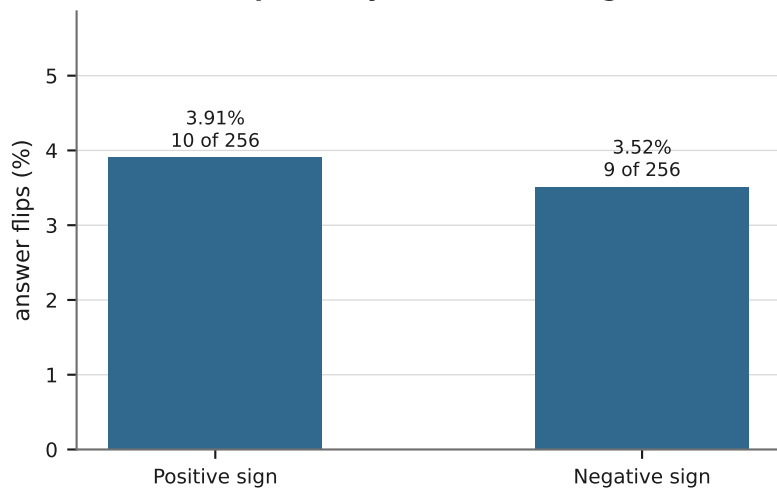

Most effects are small but measurable

Answer-token directions flip no more often than controls

Flip rate by intervention sign

Calibration prompts only. These panels describe the stimulus that was chosen before any forecast existed; they say nothing about whether hidden states predict it. That the answer-token directions flip answers at about the control rate is a limitation of the intervention family, reported in the paper. The two lower panels show the same counts by coincidence: the role split and the sign split happen to give 10 and 9 flips each.
